ABSTRACT

Kithul (*Caryota Urens*) palm is a useful tree in Sri Lanka being the sap is used as an ingredient for a large number of foods. Kithul flour also will be a good ingredient having considerable gelling property. The objectives of this study were to analyze the granular morphology of Kithul flour and study differences among flour samples from five main Kithul growing areas. Flour samples were collected from both household and commercial markets representing five main Kithul growing districts: Rathnapura, Kegalle, Kandy, Matale and Kurunegala. Microscopic measurement of starch granules was done using light microscope under the magnification power of 400 x with Magnus live USB 2.0 viewer and Image tool for windows softwar). Flour treatments did not differ with respect to granular morphology with mean length and width of starch granule being 45.5 μm , 26.4 μm , respectively. This study showed different shapes of Kithul starch granules such as spherical, oval, and irregular globular with oval shape being the most common shape (51.4% of total granules). Analyzed results revealed that there were no significant differences among Kithul flour samples obtained from five main growing districts with respect to granular morphology which could be a positive result for using composite Kithul flour from different growing areas for future food applications.

KEY WORDS: Kithul flour, *Caryota urens*, granular morphology, granular shape, Kithul growing areas

1. INTRODUCTION

Starch is the storage form of plant carbon assimilation (Vegh, 2002) formed by complex series of biochemical reaction of photosynthesis (Qiang, 2005). Starch is composed of amylose and amylopectin which are molecular entities of polysaccharide (Qiang, 2005). Differences in physico-chemical properties of these two molecules affect retrogradation, viscosity, and gel stability properties of starch (Vegh, 2002) The ratio of amylose:amylopectin in starch granules differ based on plant origin. Starch consists of alternating semi-crystalline and amorphous layers (Svilhus *et al.*, 2005)

Type of starch as well as the amount of starch are important factors for the final texture of the food product (Biliaderis, 1991) .The shape and size of the granules are important factors for the functional properties of the starch (Svilhus *et al.*, 2005), especially swelling, solubility and digestibility (Adejumo *et al.*, 2011) Franco & Ciacco, (1992) observed that the large size of starch granule are responsible for less of enzymatic susceptibility (Franco & Ciacco, 1992)

Diameter of starch granule, recently, has been found to be an essential component for food and industrial applications of starches (Campbell *et al.*, 1996). Granule distribution varies between cultivars according to the genetically controlled (Sahlstrom *et al.*, 1998) and environmental factors (Testeret *et al.*, 1991). However, granular morphology is very effective for identification of botanical source because shape, size and hilum position (Qiang, 2005) of the granules depend on the source (Preiss, 2004). As the main energy of human diet starch plays a major role. It creates a high demand for new starch source as staple food for boost population all over the world. Hence food and agro- researchers are discovering novel sources of starch, which exist in the wild. Kithul (*Caryota urens*) is an agreeable feedback

for this requirement, which is still kept as a semi-wild species.

Kithul (*Caryota urens*) is indigenous to India, Sri Lanka and Malaysia (Rajyalakshmi, 2004), while the most prominent trees in the perennial forests of highland Sri Lanka (Ynonne, 1995). It is a slow-growing, shade-tolerant (Orwa *et al.*, 2009) palm. The total number of Kithul trees found in the island amounts to 2,977,261 (largely spread in Sabaragamuwa, Central and Uva provinces), which has surveyed by National programme for Kithul Development, Ministry of traditional industries and small enterprise development (Ministry of Traditional Industries, 2009. This palm comes under the commercially beneficial trees in Sri Lanka, being used to produce large number of food and wooden products. Kithul flour is used as a main ingredient for a large number of foods (Punchihewa, 2012) such as pudding (*thalapa*), porridge (*Kenda*), rice cake (*kawum*), a sweet meat (*Dodol*) and dough of flour heated in a pan (*Rotee*) etc (Seneviratne, 2011).

As per the literature, palm starch is one of the cheapest and most available sources of food, which shows the highest productivity per land area among other starch crops (Shoon, 2000).

The objectives of this study were to analyze the granular morphology of Kithul flour and study differences among flour samples from five main Kithul growing areas to find out the possibilities to use Kithul flour from any growing area for future food applications.

2. MATERIALS & METHODS

2.1 Selection of area and sample collection

Areas were selected based on the statistics on Kithul palms by district. Five districts, namely Kurunegala (North-western

province), Matale and Kandy (Central province), and Kegalle and Rathnapura (Sabaragamuwa province) were selected for the study as the five main growing area in Sri Lanka. Six Kithul flour samples were collected from each district from both household and commercial markets.

2.2 Granular morphological variations of starch

Morphology of native starch granules was observed according to the method described by Jayakody *et al.*, 2009 with slight modifications. Starch solution was prepared by mixing with 1:1(w/v) mixture of distilled water to glycerine (1:1,v/v).The starch solution was stained with a 0.05% iodine solution and a thin smear was prepared on a glass slide with a cover slip. Microscopic measurement of Kithul starch granules was done using light microscope (HITACHI SU 6600, Japan) under the magnification power of 400 x with Magnus live USB 2.0 viewer and UTHSCSA Image tool for windows software (Developed by University of Texas, 1995-2002). The length and diameter of the granules from each starch sample obtained from five different districts were measured and the shape of granules was observed.

2.3 Statistical Analysis

Results were analyzed using one-way analysis of variance (ANOVA) at 0.05 probability level with MINITAB software package (version 14 for Windows)

3. RESULTS AND DISCUSSION

According to the statistical results of the starch granular length and width there were no any significant differences ($p > 0.05$) among samples from five districts (Table 1). Length of the granules ranged from 9.8 to 117.8 μm though mean value was 45.6 μm (Figure 1), which is compatible with previously reported value (44 μm) of *Caryota urens* pith flour (Anilakumai & Rajyalakshmi, 2000), while the

width of granules ranged from 7.0 to 56.9 μm with a mean value of 26.4 μm (Table 1).

Figure 1. Light micrograph (x400) of different size of Kithul starch granules

Table 1. Variations in granular size of Kithul flour collected from five districts in Sri Lanka

Sampling Area	Length of the granule / μm	Width of the granule / μm
Kandy	47.8 ± 20.3 ^a	26.4 ± 11.0 ^a
Kegalle	45.1 ± 16.7 ^a	29.0 ± 10.8 ^a
Kurunegala	44.0 ± 20.5 ^a	23.9 ± 8.4 ^a
Matale	45.1 ± 19.4 ^a	25.5 ± 9.4 ^a
Rathnapura	45.8 ± 19.0 ^a	27.0 ± 9.5 ^a
Mean	45.6 ± 19.1	26.4 ± 9.9

According to the literature there is no special categorization of granule size (Lindebooma *et al.*, 2004). Adejumo *et al.*, 2011 has defined the following classes based on granular size: large (25 μm), medium (10–25 μm), small (5–10 μm) and very small (<5 μm) granules. Based on this classification Kithul starch granules can be considered large as granular size falls within the range of 26–47 μm . Reported data of Cornell *et al.* (1994) exhibited that granule size may vary from 1–50 μm . When compared with the typical granule size of commercially available starch sources as 22 μm for wheat starch, 8 μm for rice starch and 38 μm for potato starch (Cornell *et al.*,

1994), Kithul starch has the highest value as 45.6 μm . According to Qiang Liu (2005), size of starch granules vary from 2-100 μm and most cereal starch granules are smaller than tuber and legume starches (Qiang.L,2005). Sago flour produced similarly from the bark of *Metroxylon sagu* tree exhibited a granular size of 28.4 μm (Yiu,P.H *et al*,2008)

Kithul starch granules exhibited three main granular shapes, namely spherical, oval and irregular globular shape (Figure 2). But five Kithul flour treatments did not show significant differences with respect to distribution of the three shapes (Table 2). The most common shape among samples from all five districts was oval shape (Percentage of granules ranging from 45.0 to 57.5%) (Table 2). Some granules exhibit their shape smoothly, while others are polyhedrons with a faceted surface (Vegh, 2002).

Granule shape is a very important characteristic to identify uniqueness of the starch. According to literature maize starch granules exhibited round and polygonal shapes while rice granule has polygonal shape, wheat granules has round and lenticular shapes and potato granules presented voluminous, oval and oyster shapes (Blandhard, 1987, Promanz, 1985 and Hoover, 2001). In the case of sago flour granular shape has been reported as oval, truncated (Sighal *et al.*, 2008)

Figure 2. Light micrograph (x400) of different shapes of Kithul starch granules as spherical, oval and irregular globular

Table 2. Variations on Granular shapes of Kithul flour collected from five districts in Sri Lanka

Sampling Area	Spherical shape %	Oval shape %	Irregular globular shape %
Kandy	22.9 ± 16.5 ^a	57.5 ± 14.1 ^a	19.6 ± 15.5 ^a
Kegalle	35.7 ± 19.7 ^a	52.3 ± 21.4 ^a	12.0 ± 10.2 ^a
Kurunegala	45.4 ± 18.7 ^a	45.0 ± 16.2 ^a	9.6 ± 6.3 ^a
Matale	38.3 ± 17.9 ^a	46.5 ± 11.0 ^a	15.2 ± 11.6 ^a
Rathnapura	33.35 ± 9.0 ^a	55.6 ± 6.4 ^a	11.0 ± 9.2 ^a
Mean	35.1 ± 17.3	51.4 ± 14.6	13.5 ± 10.8

4. CONCLUSION AND FURTHER WORK

Granular morphology studies confirmed that there was no significant difference among Kithul flour samples from five districts, and mean value of the starch granular length and width were 45.6 ± 19.1 and 26.4 ± 9.9 μm , respectively. Three types of granular shapes: Oval, spherical and irregular globular shapes were exhibited. Most common shape was oval which represented 51.4 ± 14.6 % of granules. Spherical shape got the second representative percentage contributing 35.1 ± 17.3% of granular shape while irregular globular shape had lowest value as 13.5 ± 10.8%.

According to this study, there were no significant differences among Kithul flour samples obtained from five main growing districts with respect to granular morphology which could be a positive point for using composite Kithul flour from different growing areas for future food applications.
