Corporate governance and Financing Decisions:
Evidence from listed Manufacturing Companies in Sri Lanka

Abstract
The financing decision of the organization is one of the most debated arenas of the corporate finance theory. According to the agency theory, the financing decision will contribute to solving interest conflicts between shareholders and managers. The financing decision is the way of choosing a firm's financing resources, namely choosing both the available resources and their mix in order to achieve the objective of maximization of shareholders' wealth. The aim of this study is to examine the impact of corporate governance mechanisms on financing decisions of listed manufacturing companies in Sri Lanka during the period of 2012 to 2016. The sample consists of 26 listed manufacturing companies in Sri Lanka. In this study, data was collected from secondary data sources and hypotheses are examined by using multiple regression analysis. The results reveal that board size has a significant impact on financing decisions of listed manufacturing companies in Sri Lanka. Other corporate governance variables are not found to have a significant impact on financing decisions. The firms should increase their board size for accessing more debt capital as large board size puts pressure on managers through stringent monitoring and regulatory mechanism to increase the value of the firm. However beyond a certain level, further increase in board size could lead to adverse effects.

Keywords: Corporate governance, financing decisions, Agency theory, Board size

INTRODUCTION

Corporate Governance and financing decision plays a vital role in the maximization of shareholders’ wealth. Good corporate governance is an important in increasing the market value of a firm while higher financial leverage decreases a firm value by increasing bankruptcy risk (Sheifer and Vishny, 1997). Corporate governance (CG) has been mostly applicable in developed markets and essentially to large and listed firms. In recent times, however, the term is on the development agenda of many developing countries, the reason being the realization that corporate governance is important for the promotion of sustained growth as it boosts the bottom line (Anthony and Nicholas (2006). The corporate governance has two meanings. It refers to the relationship between a firm and its stakeholders including shareholders, employees, creditors, competitors, consumers etc. In the second definition, corporate governance is seen as signifying
the mechanism for checking on and monitoring the behaviour of top management, due to the separation of ownership and control. Thus, corporate governance refers to the clear establishment of how an organization ought to be run and controlled and ensure accountability on the part of management towards owners. Studies have shown that corporate governance enhances performance (Gompers et al., 2003; Claessens et al., 2003).

An important financing decision facing firms is the choice between debt and equity capital (Glen and Pinto, 1994). The capital structure of a firm is a mix of debt and equity the firm uses to finance its operations. Capital structure decisions are crucial for any business organisation. The decision is important because of the need to maximise returns to various organisational constituencies and also because of the impact such a decision has on an organisation’s ability to deal with its competitive environment (Abor and Biekpe, 2005). The key of the firm is to choose a portfolio of capital structure that will maintain sustainability and generate more wealth. In general, a firm can choose among many alternative capital structures. It can issue a large amount of debt or very little debt. It can arrange lease financing, use warrants, issue convertible bonds, sign forward contracts or trade bond swaps. In an attempt to set a capital structure that maximises overall market value, firms do differ in the way they deal with the issue of optimising capital structure requirements.

Corporate governance refers to how companies ought to be run, directed and controlled. It is about supervising and holding to account those who direct and control the management. It is believed that, good governance generates investor goodwill and confidence. Gompers et al. (2003) assert that, good corporate governance increases valuations and boosts the bottom line. Claessens et al. (2002) also maintain that better corporate frameworks benefit firms through greater access to financing, lower cost of capital, better performance and more favourable treatment of all stakeholders.

Corporate governance has been identified in previous studies to influence firms’ financing or capital structure decisions which also affect performance (Berger et al., 1997; Friend and Lang, 1988). These empirical studies tended to focus mainly on developed economies with inconclusive results. Very little, however, has been done on corporate governance in Sri Lanka, especially with respect to firms’ financing decisions. It is crucial to determine how current issues in corporate governance affect the financing decisions of Sri Lankan firms. This paper specifically examines the impact of various variables of corporate governance on the financing decisions of firms listed manufacturing companies on the Sri Lanka during the five-year period (2012-2016).
Research problem

With sound governance structure (CS), it is much easier for organizations to obtain loans from investors as a functional corporate structure protects the interest of shareholders, increases transparency and reduces the agency conflicts. Firms with poor governance practices face more agency problems as managers of those firm’s can easily obtain private benefits due to poor CG structure.

Weak corporate governance does not only lead to poor firm performance and risky financing patterns, but is also conducive to macroeconomic crises (Claessens et al., 2002). Becht et al. (2002) identify a number of reasons for the growing importance of corporate governance; including, the world-wide wave of privatization of the past two decades, the pension fund reform and the growth of private savings, the takeover wave of the 1980s, the deregulation and integration of capital markets, the 1997 East Asia Crisis, and the series of recent corporate scandals in the USA and elsewhere. Developing countries are now increasingly embracing the concept of good corporate governance, because of its ability to impact positively on sustainable growth. The dominance of large shareholders may therefore affect the financing decisions of firms. Businesses are therefore, being compelled to apply the most scientific methods to enable them compete on the global market. The will of investors to strive for excellence and the refusal to accept mediocrity have created stiff competition in the business environment. This drive for excellence and competition has led to the demand for information by stakeholders. Corporate bodies are continually being compelled to disclose relevant information to stakeholders and the communities in which they operate. They are required to be more transparent in their dealings and to justify their investments and financing decisions. A study of the characteristics of corporate governance and the financing decisions of Sri Lankan listed firms is therefore very crucial. This present study provides empirical evidence on corporate governance and firms’ financing decisions from the context of a developing economy. Therefore this study consists of research question “To what extent corporate governance impacts on financing decision. The objective is to examine the impact of corporate governance on financing decisions of Sri Lankan listed manufacturing firms.

This paper is organized as follows: the next section provides an overview of empirical literature on the subject matter. The following section describes the research methodology. The penultimate section discusses the results of the analysis. Finally, the last section summarizes the study results and concludes the discussion.
LITERATURE REVIEW

Theoretical Literature

Corporate governance has been given various definitions by various authors. Metrick and Ishii (2002) define corporate governance from the perspective of the investor as “both the promise to repay a fair return on capital invested and the commitment to operate a firm efficiently given (that) investment”. This definition simply suggests that the nature of the governance structure of a firm has an impact on its ability to access capital markets.

The theoretical framework upon which CG and CS is based includes the agency theory free cash flow theory. Evidence from previous empirical studies has sought to confirm the effect of CG on firm performance and reviewed the theories.

Agency Theory: CG has traditionally been associated with the “principal-agent” or “agency” paradox. A “principal-agent” relationship arises when the person who owns a firm is not the same as the person who manages or controls it. Agency theory has its roots in economic theory and was developed by Jensen and Meckling (1976) and it states that shareholders who are the owners or principals of the company delegate the running of business to the managers or agents. The shareholders expect the agents to act and make decisions in the principal’s interest but the agents may make contrary decisions. Jensen and Meckling (1976) argued that the separation of ownership and control has resulted in an agency problem as the managers who act as agents might not always act in the best interests of the shareholders or owners, who are the principals of the firm. This might be due to the interests of both parties which are not aligned. Agency problem results in agency costs, which are the costs of the separation of ownership and control. Agency costs have been defined as the sum of the monitoring expenditures by the principal, the bonding expenditures by the agent and the residual costs.

Free Cash Flow Theory: According to free cash flow theory (Jensen, 1986), leverage itself can also act as a monitoring mechanism and thereby reduces the agency problem hence increasing firm value by reducing the agency costs of free cash flow. There are some consequences derived if a firm is employing higher leverage level in that managers of such firm will not be able to invest in non-profitable new projects, as doing so the new projects might not be able to generate cash flows to the firm, hence managers might fail in paying the fixed amount of interest on the debt or the principal when it’s due. It also might cause the inability to generate profit in a certain financial year that may result in failing to pay dividends to firm shareholders. Leverage might not only be able to reduce the agency costs of free cash flow, but also can increase the efficiency of the
managers. This is due to the debt market that might function as a more effective capital market monitoring. In addition, in order to obtain the debt financing, managers must show their abilities and efficiencies in managing the firm. Empirically, it has been proven that leverage proxied by bank lenders, can be substitute monitoring mechanism especially in weak CG firms, but not in the more active merger environments.

**Empirical Literature**

There have been some studies that link corporate governance and financing decisions of firms. For instance Berger et al. (1997), Friend & Lang (1988), Wen et al. (2002), and Abor (2006), show that the nature of corporate governance in a firm has an influence on its financing decisions. The main corporate governance characteristics that have been identified to impact on financing decisions of firms include board size, board composition, CEO duality, tenure of the CEO, and the CEO’s compensation. The empirical literature on governance and capital structure so far, though scanty, show varied results and appear largely inconclusive.

The board of any corporate entity is the highest decision making body entrusted with the responsibility of ensuring that the firm operates efficiently and competitively. The board size measured by the number of people that constitutes the board has a significant relationship with the financing decision of a firm according to Pfeffer & Selancick (1978), and Lipton & Lorsch (1992). Berger et al. (1997) show that firms with larger board sizes tend to have low leverage or concentrate rather on equity financing. The underlying principle is that a large board size inevitably translates into coercion from the board on managers to rather depend on less debt to enhance firm performance. A critical issue raised by Jensen (1986), however, is that firms with high leverage or a high debt ratio have larger boards. This twist introduces an issue of causality. The question is, do firms resort to high leverage because they have larger board sizes or do firms increase board sizes because they are highly leveraged? Studies on this issue are largely non-existent. However, empirical results in China by Wen et al. (2002) and by Abor in Ghana (2006) point to a positive relationship between board size and leverage. These findings presuppose that large board sizes, that exist largely due to monitoring by regulatory bodies, target higher leverage to enhance corporate value. It could also be due to the difficulty of arriving at consensus in decision-making. Such a scenario has the tendency of weakening corporate governance leading to dependence on high leverage primarily as a disciplining mechanism for firm value maximization. Furthermore, Anderson et al. (2004) point out that the cost of debt is lower for larger boards probably due to the fact that creditors view these firms as essentially having effective monitoring on their operations.
Studies have also shown that the nature of board structure typology (CEO duality) also has a relationship with the financing decisions of a firm. In this case, studies have centered on 1-tier and 2-tier board structure typologies. A firm is said to have a 1-tier board structure if the CEO combines as the board chairperson. On the other hand, in a situation where the CEO and board chair positions are occupied by separate personalities, the firm is said to be operating a 2-tier board structure. In the one-tier board structure typology, it is deemed that the two critical issues of decision making and control are vested in the same personality, which is however thought to be inappropriate (Fama & Jensen, 1983). Again, Fama and Jensen (1983) define “decision management” as the right vested in a CEO to initiate and implement new proposals warranting expenditure of the firm’s resources, while “decision control” is the right to ratify and monitor these proposals. Hence, there exists a conflict of interest and higher agency cost if these are done by the same personality signaling the lack of separation of “decision management and decision control”. Fosberg (2004) shows that a 2-tier board structure typology is characterized by higher leverage or debt: equity ratios as compared to a 1-tier leadership scenario. Abor (2006) in a Ghanaian study however found a negative relationship between 2-tier board structure typology and leverage.

The other related characteristic of corporate governance is compensation of the CEO. CEOs with attractive fixed compensation might pursue lower leverage to reduce the financial risk and keep their job for the attractive remuneration (Stulz, 1988; Harris and Raviv, 1988). However, empirical evidence has shown contradictory findings. Jensen and Meckling (1976), and Berger et al. (1997) show positive association between CEO’s compensation and capital structure of the firm. Wen et al. (2002), Friend and Hasbrouck (1988) also find a negative relationship between fixed compensation and financial leverage.

In Sri Lankan context, Nirosha and Stuart (2012) find that Sri Lankan listed companies pursue a policy of high debt with high insider ownership and CEO duality. Non-executive directors tend to have less external financing than boards with more executive directors. In general, this study finds the issue of corporate governance has important implications on the financing decisions of Sri Lankan listed firms. Nishani and Athula (2015) investigate the influence of capital structure on firm value measured in Tobin’s Q. The study has both theoretical and practical implications. While it finds evidence to generalize the notions of the three theories employed in the study, it also reveals empirically that how corporate governance variables influence capital structure decisions and firm value in the manufacturing companies in Sri Lanka.

Siromi and Chandrapala (2017) identify that there is no significant effect of corporate governance attributes except board composition & board committee on capital structure. The variable of board
composition has a significant positive effect and board committee has a negative effect on capital structure.

Based on the literature review, the following hypotheses are developed,

H₁: Board size has a significant impact on financing decision.
H₂: Board independence has a significant impact on financing decision.
H₃: CEO duality has a significant impact on financing decision.
H₄: Board meeting has a significant impact on financing decision.

METHODOLOGY

Data and variable description

Data for the study is obtained from twenty six (26) manufacturing companies listed on the Colombo Stock Exchange (CSE) covering the five (5) year period 2012-2016. For the dependent variable, the firm’s debt ratio is measured as the ratio of total debt to total assets (i.e. LEV = Leverage). For a deeper understanding of further relationships, leverage is divided into short-term leverage (STL) and long-term leverage (LTL) which are measured as the ratio of short-term debts and long-term debts to total assets respectively. Regarding the independent variables, Board size (BDS) measured by the number of board members, Board independence (BDI) measured by the ratio of independent board members to board size, CEO duality (CEO) indicates whether the company’s CEO is also chairman of the board, Dummy variable equal to 0 if the two variables are separate.

Research Model

The study follows the panel model specification for the purpose of estimating the impact of corporate governance on financing decision of listed manufacturing companies in Sri Lanka. The panel data model is as follows:

\[ Y_{it} = \alpha_i + \beta_1 X_{1it} + \beta_2 X_{2it} + \beta_3 X_{3it} + \beta_4 X_{4it} + \epsilon_{it} \]
Where $Y_{it}$ is leverage of firm $i$ at time $t$, $\alpha_i$ is a constant term, $\beta_1$, $\beta_2$, $\beta_3$ and $\beta_4$ are the beta coefficients, $X_1$, $X_2$, $X_3$ and $X_4$ are the explanatory variables used in the study, and $\epsilon_{it}$ is the error term. The specific models are as follows:

\[
\begin{align*}
STL_{it} &= \alpha_i + \beta_1 BS + \beta_2 BI + \beta_3 CEO + \beta_4 BM + \epsilon_{it} \\
LTL_{it} &= \alpha_i + \beta_1 BS + \beta_2 BI + \beta_3 CEO + \beta_4 BM + \epsilon_{it} \\
LEV_{it} &= \alpha_i + \beta_1 BS + \beta_2 BI + \beta_3 CEO + \beta_4 BM + \epsilon_{it}
\end{align*}
\]  

Where,

- $STL_{it}$ – Short-term leverage of firm $i$ at time $t$.
- $LTL_{it}$ – Long-term leverage of firm $i$ at time $t$.
- $LEV_{it}$ – Total leverage of firm $i$ at time $t$.
- $BS_{it}$ – Board size of firm $i$ at time $t$.
- $BI_{it}$ – Board independence of firm $i$ at time $t$.
- $CEO_{it}$ – CEO duality of firm $i$ at time $t$.
- $BM_{it}$ – Board meeting of firm $i$ at time $t$.

Choosing between random and fixed effects

The most basic estimator of panel data sets is the pooled Ordinary Least Squares (OLS). In the simplest case in which there are no firms specific and time specific effects the ordinary least square is the most appropriate. Johnston and Dinardo (1997) recall that the pooled OLS estimators ignore the panel structure of the data, treating observations as being serially uncorrelated for a given firm with homoscedastic errors across individuals and time periods. A more appropriate approach is therefore to estimate the model using other panel data techniques.

Hausman (1978) suggested a test to check whether the individual effects are correlated with the regressors. Under the null hypothesis no correlation between individual effects and explanatory variables, both random effects and fixed effects estimators are consistent but the random effect estimator is efficient while fixed effects are not. Under the alternative hypothesis individual effects are correlated with the regressors, the random effects estimator is inconsistent while the fixed effects estimator is consistent and efficient. The following hypotheses were tested while applying Hausman test.
H₀: There is no significant difference between co-efficient estimates.
H₁: There is a significant difference between co-efficient estimates.

If the chi.sq value is significant, H₁ will be supported. It implies that there is a significant difference between co-efficient estimates. Hence, this will lead to the rejection of random effects estimator.

Table 1 shows the summary statistics of both dependent and independent variables. The mean board size is about eight with the minimum and maximum being three and twelve respectively.
The standard deviation for board size is 1.928. With board independence, the mean ratio of 37.9% suggests that more insiders serve on these boards as against outsiders. This also suggests that these boards are relatively less independent (John and Senbet, 1998). However, the minimum and maximum of 12.5% and 66.7% is an indication that some of the boards are largely independent. On the average, 6.1% of the boards operate a 2-tier board structure. The standard deviation for CEO duality is of 0.241. Most of the firms depend on short-term debt as against long-term debt. The mean of short-term leverage is 72.8% with the standard deviation of 0.317.

**Regression Analysis**

Table 2 represents the results of multiple regression analysis to examine the impact of corporate governance on financing decision of listed manufacturing companies in Sri Lanka.

**Notes:** All regressions include a constant. Probability values in brackets. ** indicate significance at 5 per cent level.
In Table 2, the results of the Hausman specification test do not allow to reject the null hypothesis that the difference in coefficients is not systematic. Given such results, the preferred model is the Random-effects GLS because it is consistent and efficient under the circumstances. The study shows that short-term leverage, long term leverage and total leverage have a significant positive correlation with board size, thus contradicting the findings of Berger et al. (1997) who showed that firms with large board sizes employ less leverage. The positive relationship between the board size and leverage suggests that larger boards employ a high debt policy to raise corporate value. This may be due to an apparent lack of consensus building due to board size resulting in weaker corporate governance. This finding is consistent with other studies (Jensen, 1986; Wen et al., 2002; Abor, 2006). Again, this could be due to the fact that large board sizes, which are relatively more entrenched due to monitoring by regulatory bodies, make it a deliberate policy to target higher leverage for the purpose of enhancing corporate value. Therefore, as board size has a significant impact on financing decisions such as short-term leverage ($\beta=0.075018^{**}$, $P<0.05$), long term leverage ($\beta=0.073444^{**}$, $P<0.05$) and liability ($\beta=0.0.037437^{**}$, $P<0.05$), hypothesis one ($H_1$) is supported.

The results of the study show that board independence is insignificant in explaining short-term leverage, long-term leverage and total leverage. So, $H_2$ is not supported. Further CEO duality and board meeting have insignificant impact on short-term leverage, long-term leverage and total leverage ($P>0.05$). Therefore, $H_3$ and $H_4$ are not supported. The F-statistics values are 2.360245 ($P<0.05$) for short-term leverage, 1.346875 ($P<0.05$) for long-term leverage and 1.922302($P<0.05$) for total leverage which show that the corporate governance variables jointly significantly explain the variations in short-term leverage, long-term leverage and total leverage. The R-square value of 0.1349, 0.0777 and 0.1127 represent that variation of 13.49%, 7.77%, and 11.27% in short-term leverage, long-term leverage and total leverage are explained by corporate governance variables respectively.

**CONCLUSION**

The objective of this research study was to examine the impact of corporate governance on financing decision of listed manufacturing companies in Sri Lanka. Corporate governance refers to how corporate entities ought to be run, directed and controlled. It is indeed believed that better corporate governance enhances a firm’s profile through better access to finance, lower cost of capital, better performance and preferential treatment on the part of all stakeholders. Of critical
importance is the fact that the concept of corporate governance is now dominating the policy agenda of most developing nations.

This study looked at corporate governance and its impact with financing decisions of listed manufacturing firms by using data from 26 listed firms on the Colombo stock exchange covering the period 2012 to 2016. A random-effects GLS panel data regression model was employed and results show that board size influences significantly on financing decisions of firms and other corporate governance variables don’t have any impact on financing decision such as short-term leverage, long-term leverage and total leverage. In conclusion therefore, it is recommended that firms should position themselves by strengthening governance structures in order to promote their attractiveness and therefore their capacity to access financial markets.
